χ^2 Analysis: Expected vs Observed Values

| Name: | Date: | Period: |
|-------|-------|---------|
|-------|-------|---------|

 χ^2 tests the null hypothesis. The formula is:

$$\chi_2 = \Sigma \frac{(o-e)^2}{e}$$

Where o is the number of observed and e is the number of expected.

| Observed Phenotypes (o) | Expected(e) | (0-0) | (0-e) ² | (0-e) ² |
|----------------------------|-------------|-------|--------------------|--------------------|
| | | | | 6 |
| | | | | |
| | | | | |
| | | | | |
| | | | | |
| | | | | |
| | | | V2-510 012- | |

Calculate χ^2

To determine how the observed and expected values compare, we need to use the critical values of χ^2 table that follows.

χ^2 Analysis: Expected vs Observed Values

| Name: | Date: | | Period: | | | |
|--------------------------|-------------------------|------|---------|------|------|--|
| Inder soldering below ge | DEGREES OF FREEDOM (df) | | | | | |
| PROBABILITY (p) | 1 | 2 | 3 | 4 | 5 | |
| 0.05 | 3.84 | 5.99 | 7.82 | 9.49 | 11.1 | |
| 0.01 | 6.64 | 9.21 | 11.3 | 13.2 | 15.1 | |
| 0.001 | 10.8 | 13.8 | 16.3 | 18.5 | 20.5 | |

To use the table, you need to determine the "degrees of freedom". "Degrees of freedom" equals the number of categories minus 1.

To determine the critical values of χ^2 , it is standard practice to use the 0.05 p value. This signifies that if the value of our calculated χ^2 is greater than or equal to the critical value from the table, 95% of the time chance alone could not account for the difference.

USING χ^2 : WE COMPARE THE CRITICAL VALUE (FROM THE TABLE) WITH THE CALCULATED VALUE (OUR CALCULATIONS).

If the calculated value of χ^2 is greater than or equal to the critical value of χ^2 , we reject the null hypothesis and accept the alternate hypothesis concluding that there is a difference between observed and expected values.

If the calculated value of χ^2 is less than the critical value of χ^2 , we accept the null hypothesis that says there is no difference between the observed and expected values.
